Decoder

- A decoder is a combinational circuit that converts binary information from n input lines to m (maximum of 2ⁿ) unique output lines
 - n-to-m-line decoder
- A binary one-hot decoder converts a symbol from binary code to a one-hot code
 - Output variables are mutually exclusive because only one output can be equal to 1 at any time (the 1-minterm)
- Example
 - binary input a to one-hot output b
 - b[i] = 1 if a = i or b = 1 << a
 - a stands for position of 1 in b

Logic Diagram vs Block Diagram

- We can use block diagram
 - Clearly denoting the input position and output sequence

Main Usages of Decoders

- Minterm generator (最小项生成器):
 - Generate the 2^n (or fewer) minterms of n input variables. For example: a 3-8 line decoder
- Data demultiplexing (数据分配器):
 - A decoder with enable input can function as a demultiplexer a circuit that receives information from a single line and directs it to one of 2ⁿ possible output lines.
- Display decoding: (显示解码)
 - Decoders are used in display systems to select a specific output line based on the input code and drive the corresponding segment of the display.
- Address decoding:(地址解码):
 - Identify a memory cell, disk sector, or other memory or storage device, to ensure one device can communicate with the processor at one time.

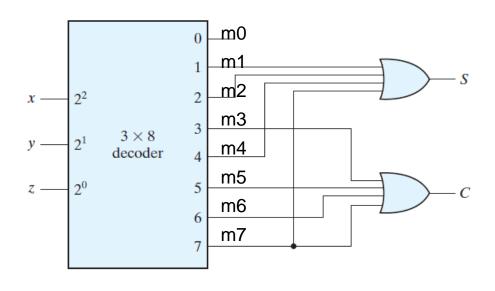

Decoder for logic implementation Example1

- Decoder can be used to implement the logic function by connecting the appropriate minterms to an OR gate.
 - Any combinational circuit with n inputs and m outputs can be implemented with an n-to-2ⁿ decoder in conjunction with m external OR gates

0	0	0	0	0
0	0	1	0	1

0	1	1	1	0
1	0	0	0	1
1	0	1	1	0
1	1	0	1	0
1	1	1	1	1

$$S(x, y, z) = \sum (1, 2, 4, 7)$$

 $C(x, y, z) = \sum (3, 5, 6, 7)$

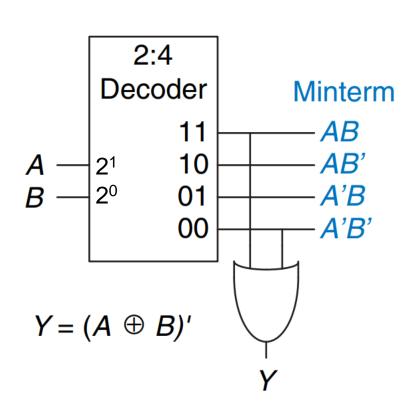

Decoder for logic implementation Example2

Exercise:

 Implement Y = A XNOR B using a 2-to-4 line decoder and external OR gate, you need to clearly write down the input and output pins

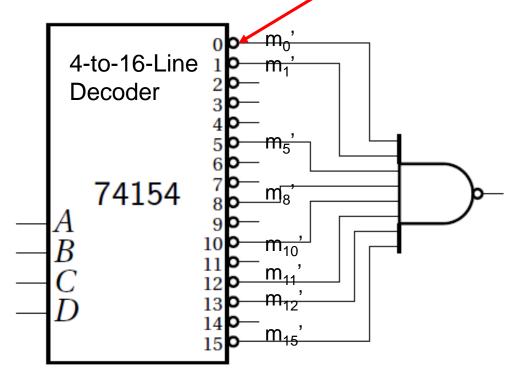

Y = A XNOR B
=
$$(A \oplus B)$$
'
= A'B' + AB
= $\sum (0, 3)$
Connect output 0 and 3
to an OR gate

Decoder for logic implementation Example3

- On Southern
- 有分科技大学 SOUTHERN UNIVERSITY OF SCIENCE AND TECHNOLOGY

- MSI 74154: 4-to-16 line decoder
 - If A = B = C = D = 0 the output 0 of the decoder is 0 while all other outputs are 1.(active low) → generate inverse of minterms
 - Example: $F(A,B,C,D) = \sum (0, 1, 5, 8,10,12,13,15)$.
 - = $[(m_0+m_1+m_5+m_8+m_{10}+m_{12}+m_{13}+m_{15})']'$
 - $=(m_0' \cdot m_1' \cdot m_5' \cdot m_8' \cdot m_{10}' \cdot m_{12}' \cdot m_{13}' \cdot m_{15}')'$

Multiplexers (MUX)

 A Multiplexer selects (usually by n select lines) binary information from one of many (usually 2ⁿ) input lines and directs it to a single output line.

Logic equation

$$Y = s_1's_0'I_0 + s_1's_0I_1 + s_1s_0'I_2 + s_1s_0I_3$$

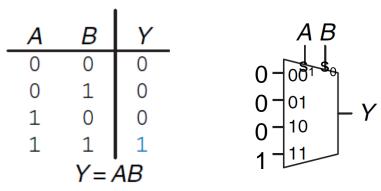

MUX Composition

- MUX = decoder + OR gate
 - The device has two control or selection lines S₁ and S₀,
 - Logic equation: $Y = s_1's_0'I_0 + s_1's_0I_1 + s_1s_0'I_2 + s_1s_0I_3$

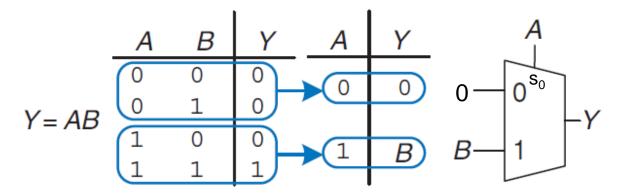

- Implement AND function using MUX
 - can be used as a look-up table
 - 4:1 multiplexer can be used (truth table)

Exercise: Implement XNOR function using

- 1) a 4:1 MUX
- 2) a 2:1 MUX

- What if only 2:1 MUX is allowed to use?
 - By using variable as data inputs

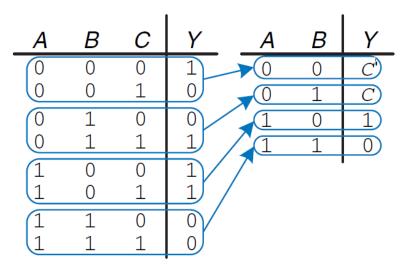

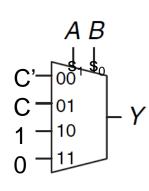

- Implement the function $Y(A,B,C) = \sum_{A,B,C} (0,3,4,5)$ with MUX

2. using 4:1 MUX

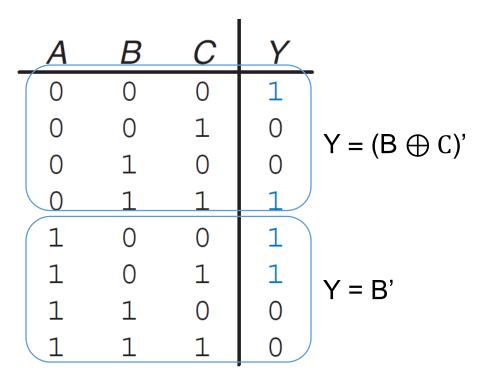

We can use 4:1 MUX
 by reducing the truth
 table to four rows by
 letting A,B as select bit
 s₀ and s₁

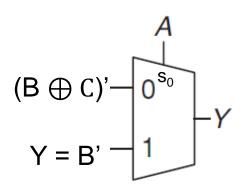

- Implement the function $Y(A,B,C) = \sum (0,3,4,5)$ with MUX
 - 3. Using 2:1 MUX?

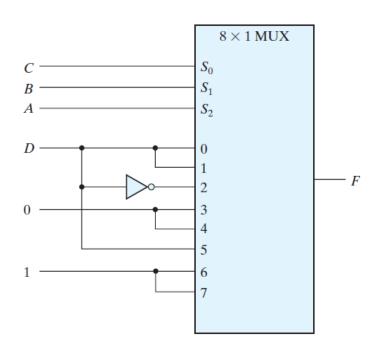

- Implement F (A, B, C, D) = (1, 3, 4, 11, 12, 13, 14, 15) with three selection inputs Multiplexer.
 - A must be connected to selection input S₂ so that A, B, and C correspond to selection inputs S₂, S₁, and S₀, respectively

MUX Expansion

 Wider multiplexers, such as 8:1 and 16:1 multiplexers, can be built with smaller multiplexers

Function table

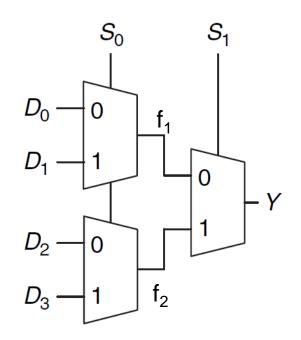

$$\begin{array}{c|cccc} S_1 & S_0 & Y \\ \hline 0 & 0 & D_0 \\ 0 & 1 & D_1 \\ \end{array} f_1 = S_0'D_0 + S_0D_1 \\ 1 & 0 & D_2 \\ 1 & D_3 \\ \end{array} f_2 = S_0'D_2 + S_0D_3$$

Logic equation

$$Y = s_1'f_1 + s_1f_2$$

= $s_1(s_0'D_0 + s_0D_1) + s_1(s_0'D_2 + s_0D_3)$
= $s_0's_1'D_0+s_0s_1'D_1+s_0's_1D_2+s_0s_1D_3$

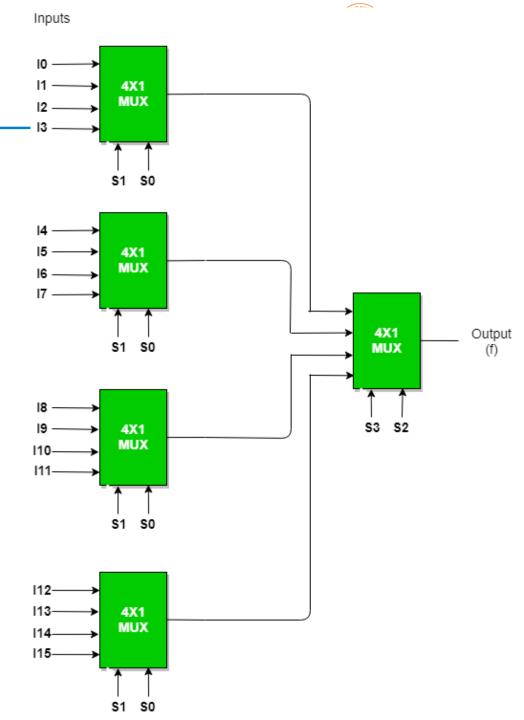

4:1 MUX with three 2:1 MUX

MUX Expansion

- How to build a 16-to-1 multiplexer using five 4-to-1 multiplexers?
 - $16 = 2^4$
 - 4 bits for selection

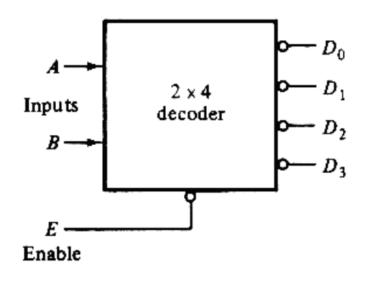

Exercise: How to build a 8-to-1 multiplexer using two 4-to-1 MUX and a 2-to-1 MUX? You must carefully connect the selection and input pins

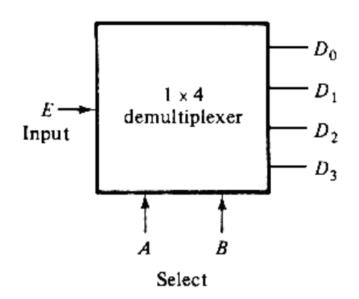

Demultiplexer

- A decoder with enable input can function as demultiplexer
 - a circuit that receives information from a single line and directs it to one of 2ⁿ possible output lines.
 - Because decoder and demultiplexer operations are obtained from the same circuit, a decoder with an enable input is referred to as a demultiplexer.

Outline

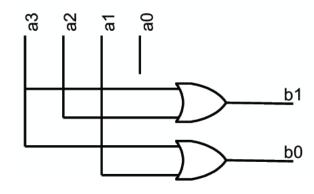

- Decoder
- Multiplexer
- Encoder
- Gate Behavior

Encoder

- An encoder is an inverse of a decoder
- Encoder is a logic module that converts a one-hot input signal to a binary-encoded output signal
- Other input patterns are forbidden in the truth table
- Example: a 4->2 encoder

_ a ₃	a_2	a ₁	a_0	b ₁	b_0
0	0	0	1	0	0
0	0	1	0	0 1	1
0			0	1	0
1	0	0	0	1	1

$$b_0 = a_3 + a_1$$

 $b_1 = a_3 + a_2$

Encoder

- A combinational logic that performs the inverse operation of a decoder
 - Only one input has value 1 at any given time
 - Can be implemented with OR gates
- However, when both D3 and D6 goes 1, the output will be 111 (ambiguity)! illegal inputs !Use priority encoder!

•	Outputs			Inputs							
-	z	y	X	D ₇	D ₆	D ₅	D ₄	D_3	D ₂	D ₁	D ₀
	0	0	0	0	0	0	0	0	0	0	1
$X = D_4 + D_5 + D_6 + D_7$	1	0	0	0	0	0	0	0	0	1	0
$y = D_2 + D_3 + D_6 + D_7$	0	1	0	0	0	0	0	0	1	0	0
•	1	1	0	0	0	0	0	1	0	0	0
$z = D_1 + D_3 + D_5 + D_7$	0	0	1	0	0	0	1	0	0	0	0
	1	0	1	0	0	1	0	0	0	0	0
	0	1	1	0	1	0	0	0	0	0	0
	1	1	1	1	0	0	0	0	0	0	0

Priority Encoder

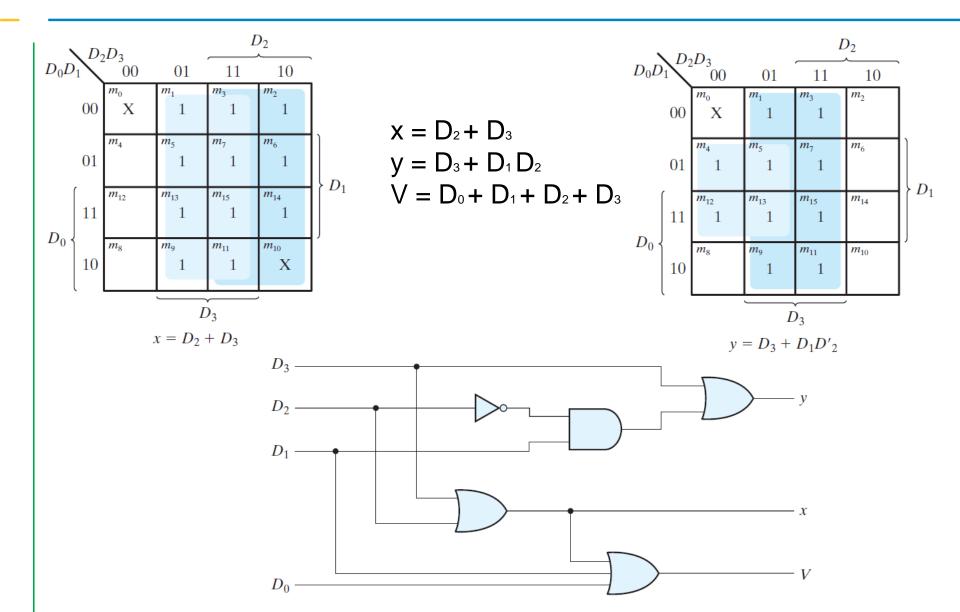

- Ensure only one of the input is encoded
- D₃ has the highest priority, while D₀ has the lowest priority.
- X is the don't care conditions, V is the valid output indicator.

	Inputs			Outputs			
D_0	D ₁	D ₂	D ₃	X	y	V	
0	0	0	0	X	X	0	
1	0	0	0	0	0	1	
X	1	0	0	0	1	1	
X	X	1	0	1	0	1	
X	X	X	1	1	1	1	

$$V = D_0 + D_1 + D_2 + D_3$$

- Decoder
- Multiplexer
- Encoder
- Gate Behavior

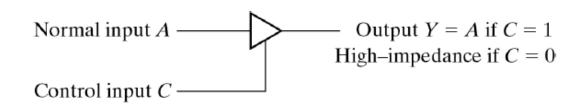

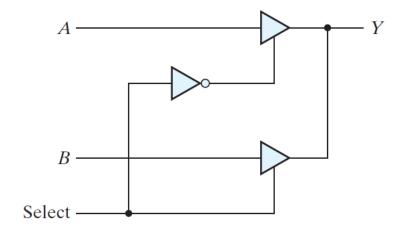

Tri-state

• Tri-state driver (buffer) has three possible output states: 0, 1, Z (high impedance).

E	Α	Y
0	0	Z
0	1	Z
1	0	0
1	1	1

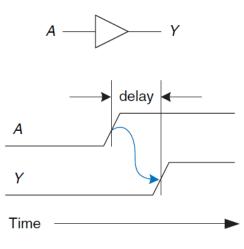

Sel	Υ
0	Α
1	В

2:1 MUX using tri-state

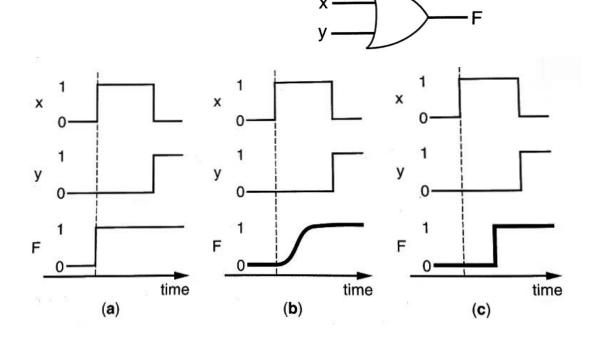

Gate Delays

 When the input to a logic gate is changed, the output will not change immediately. The output of the gate experiences a propagation delay in response to changes in the input.

delay between an input change and the subsequent output change for a buffer

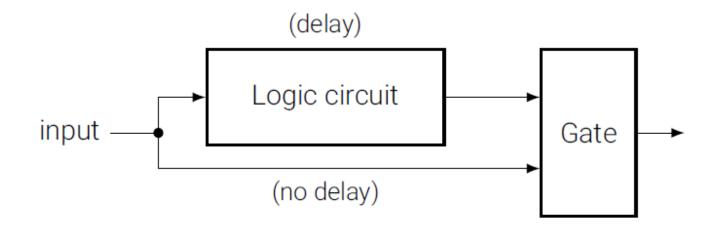

- (a) ideal behavior without gate delay
- (b) a more realistic illustration
- (c) switching incorporating the delay

Hazard (Glitches)

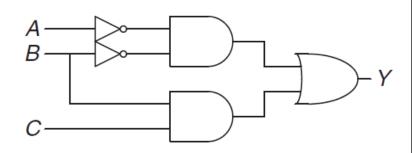

- Because of circuit delays, the transient behavior of a combinational logic circuit may differ from what is predicted by steady-state analysis.
- A timing hazard may occur when the output produces a short pulse (glitch) at a time when steady-state analysis does not predict a change.

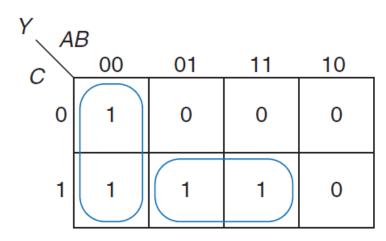

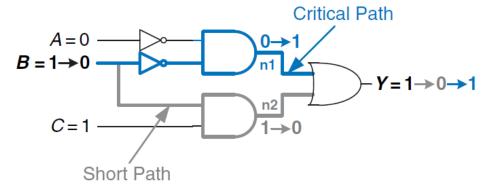

Glitch Example

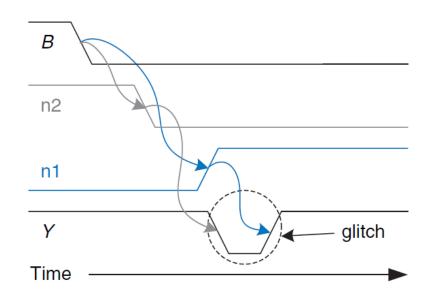

• What happens when A = 0, C = 1, B falls?

$$Y = A'B' + BC$$

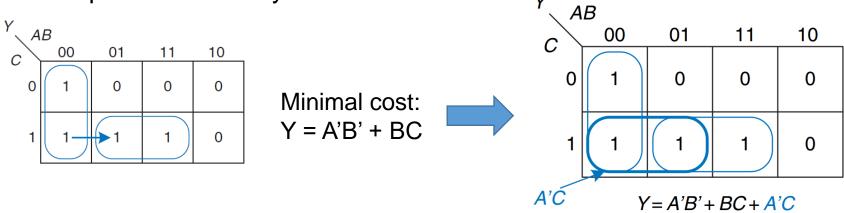

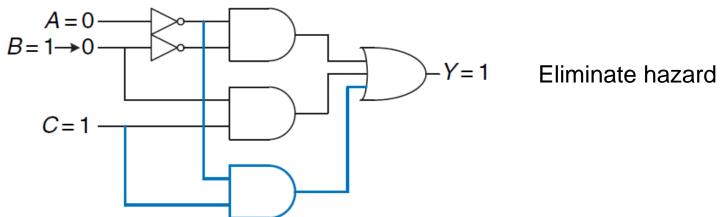

Fixing glitches

 A hazard occurs when there is a transition across the boundary of two prime implicants

• To eliminate hazards, add another circle that covers the prime

implicant boundary

Why Understand Glitches?

- As long as we wait for the propagation delay to elapse before we depend on the output, glitches are not a problem, because the output eventually settles to the right answer.
- It's important to recognize a glitch: in simulations for example
- Can't get rid of all glitches simultaneous transitions on multiple inputs can also cause glitches
